### **Preface**

For my individual project I have lots of freedom in the technical choices. However, every technical choice that I make must be validated with sources to prove it is indeed a good decision. To research what choices I should make, I looked for the most important best practises in the context of eCommerce. Here are the most important non-functional requirements according to (Technologies, 2021): **Performance, Scalability, Security, Maintainability, Usability.** These non-functional requirements also allow me to touch all the learning outcomes.

### How can I optimize page loading speed?

In today's competitive e-commerce landscape, page load speed is a critical factor in user satisfaction and conversion rates. According to research about page loading speeds (Wiegand, 2022) an e-commerce website must load within 1 second or less to retain potential customers effectively. Websites that take longer than this threshold risk losing a significant portion of their visitors, as users tend to abandon pages that are slow to load.

Given the importance of swift page loading, this research aims to explore and identify key strategies for optimizing response times in e-commerce applications. By focusing on techniques and best practices that address common performance bottlenecks, this study seeks to provide actionable insights that can help me achieve faster loading speeds and improve overall user experience. This research will cover critical optimization strategies, including image and media management, caching techniques, hosting performance, and the reduction of render-blocking resources.

#### **Best practices**

According to research on page speed optimization (Schaff, 2019) and (MOZ, 2021), several key strategies can significantly enhance your website's performance. The following table outlines these essential optimizations as well as potential upgrades to take your site's speed to the next level.

Table based on the information in (Schaff, 2019)

| Criteria                     | Description                    | Tier                  |
|------------------------------|--------------------------------|-----------------------|
| Browser Caching / Expires    | Essential for improving        | Tier I (Deal-Breaker) |
| Headers / Cache Static       | performance; prevents re-      |                       |
| Content                      | downloading assets on every    |                       |
|                              | page load.                     |                       |
| Image Compression and        | Critical for reducing          | Tier I (Deal-Breaker) |
| Optimization / Page Size     | download size and improving    |                       |
|                              | load times.                    |                       |
| Time to First Byte (TTFB) /  | Vital for improving server     | Tier I (Deal-Breaker) |
| Page Caching                 | response times and reducing    |                       |
|                              | load on the server through     |                       |
|                              | caching.                       |                       |
| Render-blocking Resources    | Newer best practice            | Tier II (Upgrade)     |
| / Critical CSS / Async CSS & | improves performance           |                       |
| JS                           | significantly when combined    |                       |
|                              | with other optimizations.      |                       |
| JavaScript Execution Time /  | Manage JavaScript execution    | Tier II (Upgrade)     |
| 3rd Party Scripts            | and limit 3rd party scripts to |                       |
|                              | optimize performance.          |                       |
| Unused CSS & JS (Code        | Further optimization by        | Tier II (Upgrade)     |
| Coverage)                    | removing unnecessary global    |                       |
|                              | CSS and JS to reduce bloat.    |                       |
| Minification                 | Important for reducing asset   | Tier II (Upgrade)     |
|                              | sizes and improving            |                       |
|                              | download times.                |                       |
| CDN                          | Easy win for improving load    | Tier II (Upgrade)     |
|                              | times and reducing server      |                       |

| load by using a content |  |
|-------------------------|--|
| delivery network.       |  |

Table based on the information in (MOZ, 2021)

| Criteria                     | Description  |  |
|------------------------------|--|--|
| Enable Compression           | Use Gzip to reduce the size of CSS, HTML, and JavaScript           |  |
| Eliable Compression          | files. Avoid gzip for images; compress them separately.            |  |
| Minify and Pundla            | Minify CSS, JavaScript, and HTML by removing unnecessary           |  |
| Minify and Bundle Resources  | characters and comments. Combine files to reduce the               |  |
| Resources                    | number of requests.  |  |
| Reduce Redirects             | Minimize redirects to decrease wait times for HTTP request-        |  |
| Reduce Redirects             | response cycles and speed up loading.                              |  |
| Remove Render-Blocking       | Avoid or minimize JavaScript and CSS that blocks page              |  |
| Resources                    | rendering to speed up load times.                                  |  |
| Lavaraga Province Cashing    | Set caching to store data so repeat visitors don't reload the      |  |
| Leverage Browser Caching     | entire page. Manage caching expiration using tools like YSlow.     |  |
| Improve Server Peenence      | Optimize server performance to achieve a response time             |  |
| Improve Server Response Time | under 200ms. Address issues like slow database queries and         |  |
| Tille                        | insufficient memory.   |  |
| Use a Content Distribution   | istribution Distribute content across multiple servers globally to |  |
| Network (CDN)                | enhance speed and reliability.                                     |  |
|                              | Resize and compress images appropriately. Use the right            |  |
| Optimize Images              | format (PNG for graphics, JPEG for photos) and CSS sprites to      |  |
|                              | reduce HTTP requests.  |  |
| HTTP/2                       | Enable HTTP/2 to process multiple requests concurrently,           |  |
| 1111172                      | improving page load speed.   |  |
| Preconnect / Prefetch /      | Use techniques to pre-establish connections or fetch               |  |
| Preload                      | resources ahead of time to speed up loading.                       |  |
| First Paint & First          | Track when the first visual change or content appears on the       |  |
| Contentful Paint             | screen to gauge initial load times.                                |  |
| First Meaningful Paint       | Measure when the main content of the page becomes visible          |  |
| Thist Meaningful Faint       | to the user.   |  |
| Time to Interactive          | Determine when the page is fully interactive and usable by the     |  |
| Time to litteractive         | user.  |  |
| DOM Content Loaded           | Monitor when the HTML document has been completely                 |  |
| DOM Content Loaded           | loaded and parsed.   |  |

The website (Pingdom tools, n.d.) can be used to test my website to see if there are any possible performance upgrades. Here are the mentioned techniques from the website.

| Criteria                      | Description                                  |  |
|-------------------------------|--|--|
| Compress components with gzip | Compress files like CSS, HTML, and           |  |
|                               | JavaScript to reduce size.                   |  |
| Add Expires headers           | Set expiration dates for cacheable resources |  |
|                               | to reduce load times.                        |  |
| Use cookie-free domains       | Serve static content from domains that don't |  |
|                               | send cookies, reducing data overhead.        |  |
| Avoid URL redirects           | Minimize redirects to improve page load      |  |
|                               | times.                                       |  |

| Reduce DNS lookups           | Reduce the number of domain name system         |  |
|------------------------------|---|--|
|                              | queries to speed up the page load.              |  |
| Avoid empty src or href      | Ensure all src or href attributes are filled to |  |
|                              | prevent unnecessary requests.                   |  |
| Put JavaScript at the bottom | Move JavaScript to the bottom of the page to    |  |
|                              | prevent it from blocking page rendering.        |  |

Table based on the information on (Tips to improve website speed | How to speed up websites, n.d.) and (What is lazy loading?, n.d.).

| Criteria                           | Description  |  |
|------------------------------------|--|--|
| Optimize Images                    | Reduces image load time by compressing   |  |
|                                    | images and lowering their resolution and dimensions. This minimizes the size of the    |  |
|                                    |  |  |
|                                    | image files, improving overall page load   |  |
| Limit the Number of HTTP Requests  | speed. Fewer HTTP requests mean fewer round trips                                      |  |
| Limit the Number of HTTP Requests  | to the server, reducing load times. Minimizing   |  |
|                                    | the number of assets loaded (images,   |  |
|                                    | scripts, etc.) boosts the page's loading   |  |
|                                    | performance.   |  |
| Use Browser HTTP Caching           | Saves static files in a temporary cache,   |  |
| Ose blowser HTTP Cacining          | allowing returning visitors to load pages  |  |
|                                    | faster without fetching all assets again. This   |  |
|                                    | shortens load time for repeat visitors.  |  |
| Remove Unnecessary Render-blocking | Prevents the loading of non-essential code   |  |
| JavaScript                         | before the important page content, ensuring  |  |
|                                    | the main page elements load quicker,   |  |
|                                    | reducing initial load time.  |  |
| Limit the Use of External Scripts  | Reduces reliance on third-party scripts,   |  |
|                                    | which can delay page loading and cause   |  |
|                                    | layout shifting. By limiting external scripts,   |  |
|                                    | the page loads more smoothly and faster.   |  |
| Limit Redirect Usage               | Reducing the number of redirects prevents  |  |
|                                    | additional delays in reaching the final  |  |
|                                    | destination page, speeding up the time it  |  |
|                                    | takes for a user to access the desired   |  |
|                                    | content.   |  |
| Minify CSS and JavaScript Files    | Eliminating unnecessary characters and   |  |
|                                    | whitespace from code reduces file sizes,   |  |
|                                    | resulting in faster loading times and lower  |  |
| Has Effective Third and Co.        | bandwidth usage.   |  |
| Use Effective Third-party Services | Ensures that key functions such as hosting,  |  |
|                                    | DNS resolution, caching, and cybersecurity   |  |
|                                    | are handled efficiently. Fast hosting, DNS   |  |
|                                    | services, and CDN caching help deliver   |  |
| LazyLoading                        | content quickly.   |  |
| Lazy Loading                       | Defers loading of certain resources (like images) until needed, improving initial page |  |
|                                    | load speed. Reduces load times for images  |  |
|                                    | toau speed. Reduces toad tiffles for images  |  |

| below the fold, saving bandwidth and |
|--------------------------------------|
| improving performance.               |

With all this information it makes it easier to optimize my page loading speeds. By for example starting with the most appearing criteria such as image compression and caching and slowly working my way through the list of all the optimizations.

### Performance test

In this section I will test the performance of my website

### How many concurrent users should my website be able to handle?

### Competitive analysis

In the area of scalability there are 2 main factors: Hosting and Architecture. But before getting into that, how many users should my website be able to handle? Here is a comparison of different eCommerce websites and their average visits per day

| eCommerce Website | Average Visits per Day |
|-------------------|------------------------|
| Bol.com           | 576.700                |
| Amazon.com        | 27.400.000             |
| Aliexpress.com    | 2.300.000              |
| Raphnet-tech      | 143                    |
| Azerty.com        | 4.800                  |
| Marktplaats.nl    | 270.000                |

I was originally thinking to make something like raphnet-tech. But this would be no challenge in scalability. Therefore, I will challenge myself and choose something more difficult, like bol.com.

With the following formula from the source (Dehran, 2024). I can calculate the concurrent users bol.com handles. The values I input in the formula are found on (Bol.com Website Traffic, Ranking, Analytics [August 2024], 2024)

Concurrent Visitors = Per Day visits / Peak hours \* (60/Average duration per visit in minutes)

Concurrent Visitors = 576,700 / 4 \* (60 / 8) = 1,086,562.5

So roughly a million. I will try to build a website that can scale out to handle one million users at the same time.

# Which software architecture provides performance and efficient scalability up to one million concurrent users?

I am looking for an architecture which can scale out efficiently to handle one million concurrent users. With that in mind, it could help filter out architectures.

Best architecture practises according to (Perco, 2024). Marked in green are the pros which I look for in an architecture. Marked in red are the cons which are a dealbreaker for my project.

| Architecture Type      | Pros                                    | Cons   |
|------------------------|---|--|
| Monolithic Ecommerce   | - <b>Simplicity</b> : Easy to develop,  | - Scalability issues: Hard to                |
| Architecture           | deploy, and manage.                     | scale specific parts.                        |
|                        | - <b>Reliability</b> : Predictable with | - <b>Rigidity</b> : Changes affect the       |
|                        | tight integration.                      | entire system.                               |
| Microservice Ecommerce | - Scalability: Independent              | - <b>Complexity</b> : Requires               |
| Architecture           | scaling of services.                    | managing multiple services.                  |
|                        | - <b>Flexibility</b> : Easier to update | - <b>Resource-intensive</b> : Higher         |
|                        | and maintain specific parts.            | overhead.                                    |
| Two-Tier Ecommerce     | - Performance: Improves                 | <ul> <li>Limited scalability: Can</li> </ul> |
| Architecture           | performance by distributing             | become a bottleneck as user                  |
|                        | tasks.                                  | base grows.                                  |
|                        | - Easily manageable:                    | - <b>Security risks</b> : More               |
|                        | Separation of client and                | exposure points.                             |
|                        | server logic.                           |  |
| Three-Tier Ecommerce   | - Scalability: Each layer can           | - <b>Complexity</b> : Harder to              |
| Architecture           | be scaled independently.                | manage with more                             |
|                        | - <b>Flexibility</b> : Easier to modify | components.                                  |
|                        | individual layers.                      | - <b>Cost</b> : Potentially higher           |
|                        |   | operational costs.                           |
| Headless Ecommerce     | - <b>Flexibility</b> : Use any          | - <b>Complexity</b> : Requires               |
| Architecture           | frontend for different                  | advanced skills to manage.                   |
|                        | devices.                                | - Integration challenges:                    |
|                        | - Enhanced user                         | Connecting multiple                          |
|                        | experience: Quick updates               | frontends to the backend.                    |
|                        | to frontend.                            |  |
| SaaS Ecommerce         | - Cost-effective: Low initial           | - Limited control:                           |
| Architecture           | investment.                             | Dependent on third-party                     |
|                        | - <b>Maintenance-free</b> : Provider    | provider.                                    |
|                        | manages updates and                     | - Customization limits: Less                 |
|                        | security.                               | flexible than o <mark>ther</mark>            |
|                        |   | architectures.                               |

Here are the most common types of eCommerce architecture according to (BigCommerceTeam, Ecommerce Website architecture (Best Practices + Your Options), 2024).

| Architecture | Pros                          | Cons                           |
|--------------|-------------------------------|--------------------------------|
| Two-tier     | - <b>Simplicity</b> : Easy to | - Limited scalability:         |
|              | implement for smaller         | Struggles with handling larger |
|              | businesses.                   | data or complex logic.         |
|              | - Performance: Allows fast    |                                |

|            | client-server communication.  | <ul> <li>Performance: Can degrade as demands grow.</li> </ul>   |
|------------|---|---|
| Three-tier | - Scalability: Independent scaling of presentation, business, and data layers Flexibility: Each layer can be developed and maintained separately. | - Complexity: More challenging to set up and maintain Cost: Requires more infrastructure, leading to higher expenses.                       |
| SaaS       | - Quick setup: Easy to launch for new businesses Low maintenance: Provider handles hosting, updates, and security.                                | - Limited control: Customization and configuration options are limited Dependence: Relies on the SaaS provider for updates and performance. |

With my preferences we can narrow down the decision to the following architectures: **Microservice Architecture, Three-Tier Architecture, Headless Architecture.** Here is a closer look on those 3 architectures.

| Approach            | Pros                                | Cons                                       |
|---------------------|-------------------------------------|--|
| Headless E-commerce | - Flexibility and Agility:          | - Complex Implementation:                  |
|                     | Enables quick adaptation to         | Requires integration of                    |
|                     | customer expectations and           | various technologies and can               |
|                     | market trends.                      | complicate the development                 |
|                     | - Seamless Omnichannel              | process.                                   |
|                     | Experiences: Delivers               | - Dependency on APIs:                      |
|                     | consistent shopping                 | Relies heavily on APIs, which              |
|                     | experiences across multiple         | can lead to issues if not                  |
|                     | channels.                           | managed properly.                          |
|                     | <ul> <li>Scalability and</li> </ul> | <ul> <li>Increased Maintenance:</li> </ul> |
|                     | Performance: Allows                 | Requires ongoing                           |
|                     | independent scaling of front-       | management of multiple                     |
|                     | end and back-end systems,           | technologies and platforms.                |
|                     | improving performance               |  |
|                     | during high traffic.                |  |
| Microservices       | - Scalability and Resilience:       | - Higher Complexity:                       |
|                     | Allows independent scaling          | Managing multiple                          |
|                     | based on demand, improving          | microservices can lead to                  |
|                     | resource allocation.                | increased architectural                    |
|                     | - Agility and Innovation:           | complexity. Inter-service                  |
|                     | Fosters an autonomous               | - Communication                            |
|                     | development approach,               | Overhead: Requires efficient               |
|                     | accelerating innovation and         | communication between                      |
|                     | deployment.                         | services, which can                        |
|                     | - Fault Isolation: Issues in        | introduce latency.                         |
|                     | one service do not affect the       | - Deployment Challenges:                   |
|                     | entire system, enhancing            | Managing deployments of                    |
|                     | reliability and maintenance         | numerous independent                       |
|                     | <mark>ease.</mark>                  | services can be                            |
|                     |                                     | cumbersome.                                |

### Information based off (Hasan, 2023).

| Architecture  | Pros  | Cons  |
|---------------|---|---|
| 3-Tier        | <ul> <li>Scalability: Independent scaling of each tier.</li> <li>Maintainability: Better organization improves maintainability.</li> </ul>  | - Scalability: Centralized design can introduce bottlenecks Complexity: Complexity in managing interactions between tiers.  |
| Microservices | - Scalability: Highly scalable; individual services can be scaled independently Maintainability: Loose coupling allows independent updates. | - Complexity: Increased complexity in managing numerous services Performance: Communication overhead can introduce latency. |

| Criteria                | Three-Tier Architecture        | Microservices Architecture     |
|-------------------------|--------------------------------|--------------------------------|
| Modularity              | More modular than              | Highly modular, with each      |
|                         | monolithic architecture.       | service focusing on a specific |
|                         |                                | function.                      |
| Codebase Separation     | Allows separation of           | Enables high separation        |
|                         | application codebase into      | between application parts,     |
|                         | distinct parts.                | enhancing flexibility.         |
| Deployment Independence | Components can be              | Components can also be         |
|                         | deployed independently,        | deployed independently, but    |
|                         | simplifying the deployment     | requires more complex          |
|                         | process.                       | management.                    |
| Security Benefits       | Separation reduces the         | Offers security benefits, as   |
|                         | impact of breaches on other    | issues in one microservice     |
|                         | components.                    | won't necessarily affect       |
|                         |                                | others.                        |
| Performance             | Issues in one layer can affect | Performance is improved;       |
|                         | overall app performance.       | issues in one service do not   |
|                         |                                | cause the entire app to fail.  |
| Complexity              | Simpler to build, deploy, and  | More complex to create and     |
|                         | manage.                        | manage due to numerous         |
|                         |                                | individual components.         |
| Scalability             | Scalable, but less efficient   | Highly scalable with granular  |
|                         | than microservices for         | scaling capabilities for       |
|                         | complex apps.                  | individual components.         |
| Deployment Environment  | Suitable for applications      | Best for distributed           |
|                         | deployed on one or a few       | environments that maximize     |
|                         | servers.                       | scalability and resilience.    |

| <b>Development Processes</b> | Suitable for teams with      | Ideal for teams with         |
|------------------------------|------------------------------|------------------------------|
|                              | simpler development          | advanced CI/CD pipelines     |
|                              | operations.                  | capable of managing          |
|                              |                              | multiple services.           |
| IT Team Readiness            | Better fit for small or less | Requires a more experienced  |
|                              | experienced IT teams.        | IT team to support the       |
|                              |                              | complexity of microservices. |

Information based off (BigCommerceTeam, Ecommerce Microservices vs. Monolith Models vs Headless Commerce, 2024)

| Architecture Type | Pros   | Cons   |
|-------------------|--|--|
| Microservices     | - Independent Scaling: Each service can scale individually, preventing backend slowdowns from frontend traffic Customization Opportunities: Businesses can select specific services tailored to their needs, enabling better personalization Rapid Implementation: Decentralized teams can deploy updates faster, improving responsiveness to market changes Best-of-Breed Solutions: Allows the use of specialized services from different providers rather than a single, all-in-one solution. | - Requires Organizational Changes: Moving to microservices may necessitate restructuring teams for better collaboration May Need Infrastructure Updates: New tools may be required for managing microservices, adding complexity Potential High Costs: Fully decoupled systems can be expensive due to multiple service providers. |
| Headless Commerce | - Flexible Content Delivery: Front-end and back-end can operate independently, enabling easier updates Agility in Customer Service: Brands can quickly adapt to customer expectations and market trends Multiple Front-End Options: Different user interfaces can be created while using a single back-end system, enhancing the customer experience.  | - Incremental Transition Challenges: Transitioning can be complex, as it requires gradual separation of components Potential Complexity: Managing multiple front-ends can introduce operational challenges API Dependency: Reliance on APIs can lead to risks if any API issues occur.   |

In conclusion, I have the option of choosing either a Microservice Architecture, Three-Tier Architecture or a Headless Architecture. While the microservice architecture excels in scalability, based off my research, all three options score similarly on the non-functional requirements I was considering. I could consider not choosing a Three-Tier because it is inefficient to scale, and efficient scalability is one of my main focusses in this project which would leave the decision between a Microservice Architecture or a Headless Architecture.

# How does my website's performance scale as the number of concurrent users increases?

Load test the website

# Which type of hosting provides high performance and automatic scaling?

#### **Best Practices**

The type of hosting not only impacts the performance but also the scalability. With a good host you will be able to easily scale your application automatically. I compared hosting services while looking for eCommerce best practises.

Best hosting options according to (Newland, 2024)

| Hosting Option           | Description  |
|--------------------------|--|
| Cloud Hosting            | Offers flexibility and scalability, allowing resources to be adjusted as needed. Ideal for sites with fluctuating traffic or rapid growth. Options include VPS, managed cloud, or PaaS. Cost-effective with a pay-as-you-go model. |
| Dedicated Server         | Provides maximum control and performance, ensuring consistent operation for large B2B sites with complex requirements. A dedicated server is more expensive but guarantees high uptime and performance.                            |
| Enterprise-grade Hosting | Included with many B2B SaaS platforms, this hosting simplifies setup and reduces inhouse technical needs. Scaling is automatic, and costs are predictable as part of a subscription fee.   |

Best hosting options according (Low, 2024)

| Hosting Type      | Description  |
|-------------------|--|
| Shared Hosting    | Limited scaling options, usually better for small sites.                         |
| VPS Hosting       | Easier to scale by adding more resources to your virtual server.                 |
| Cloud Hosting     | Designed for scaling, allows you to add or remove resources quickly.             |
| Dedicated Hosting | High scalability by upgrading hardware, best for large sites with heavy traffic. |

Hosting options according to this ecommerce blog (Samuelito, 2024)

| Hosting Type   | Description                              |
|----------------|--|
| Shared Hosting | Most affordable option, but performance  |
|                | may suffer under high traffic, making it |
|                | unsuitable for large eCommerce sites.    |

| VPS Hosting       | A good balance between cost and                |
|-------------------|--|
|                   | performance, suitable for growing              |
|                   | businesses with moderate traffic needs.        |
| Dedicated Hosting | Offers maximum performance, security, and      |
|                   | control, ideal for large-scale operations but  |
|                   | comes with a higher cost.                      |
| Cloud Hosting     | Provides flexibility and scalability, allowing |
|                   | you to pay for only the resources used,        |
|                   | making it great for fluctuating traffic.       |

Based solely on performance, **Shared Hosting** isn't a viable option. In my experience, shared hosting does suffer in terms of performance. This leaves the choice to one of the following: **VPS Hosting**, **Dedicated Hosting** and **Cloud Hosting**.

Based on Scalability, All the hosting options are capable, but since most **cloud and enterprise-grade hosts are designed for auto-scaling**, they are the most practical choice. If, for some reason, I decide not to go with one of those, I would choose **VPS hosting** because it's easy to scale. While dedicated hosting is an option in theory, it would take a lot of time to set up manually, so it would be more of a last resort.

Validate scalability here

# What are the best practices for enhancing and maintaining security in eCommerce platforms?

### **Best Practices**

To find the best practises for security I checked multiple websites and listed the best practises they mention.

Here are the best practises according to (Elitery, 2022)

| E-Commerce Security Tips                | Description                                   |
|---|---|
| Use SSL and Follow PCI DSS Security     | Secure Socket Layers (SSL) are essential for  |
| Standards                               | website authentication and data protection.   |
|   | Adhering to PCI DSS security standards        |
|   | enhances the security of financial            |
|   | transactions, helping validate credit card    |
|   | payments and preventing fraudulent            |
|   | transactions.                                 |
| Complete Website With DDoS and Firewall | DDoS attacks can render online banking sites  |
| Application                             | inaccessible. Utilizing reliable third-party  |
|   | applications like CloudFlare and Sucuri can   |
|   | mitigate DDoS attacks. Firewalls are also     |
|   | critical for protecting against SQL Injection |
|   | and cross-site scripting (XSS) attacks.       |
| Always Update                           | Many security incidents arise from outdated   |
|   | systems. Regular updates are necessary to     |
|   | safeguard your e-commerce site against        |
|   | vulnerabilities that intruders can exploit    |
|   | through old code.                             |
| Have Layered Security                   | Implementing multi-factor authentication,     |
|   | stronger passwords, address verification      |
|   | systems (AVS), and security warning systems   |
|   | can enhance e-commerce security. If your      |
|   | site integrates with external APIs, ensure    |
|   | verification and encryption measures are in   |
|   | place at each gateway.                        |
| Selected Data Selection                 | Not all data should be stored in the backend, |
|   | especially sensitive information like         |
|   | customer credit card data. Compliance with    |
|   | PCI DSS certification requires that sensitive |
|   | data not be stored on the transaction site,   |
|   | even if encrypted.                            |

Best practises according to (Derachits, 2024)

| Best Practice                       | Description                                 |
|-------------------------------------|---|
| Embrace Multi-Factor Authentication | Implement multi-factor authentication       |
|                                     | methods like 2-step verification to enhance |
|                                     | access security.                            |

| Use Stronger Passwords              | Require strong passwords for accounts,       |
|-------------------------------------|--|
|                                     | incorporating special characters, numbers,   |
|                                     | and varying letter cases.                    |
| Keep Your E-commerce Website Up-to- | Regularly update software to patch           |
| Date                                | vulnerabilities and maintain the latest      |
|                                     | security measures.                           |
| Use HTTPS Security                  | Switch from HTTP to HTTPS by using SSL to    |
|                                     | encrypt sensitive customer data during       |
|                                     | transactions.                                |
| Use a Firewall                      | Employ firewalls to monitor and block        |
|                                     | suspicious traffic while allowing authorized |
|                                     | access to your site.                         |
| Only Store Necessary Customer Data  | Limit the collection and storage of customer |
|                                     | data to only what is essential for business  |
|                                     | operations.                                  |
| Have a Secure E-commerce Platform   | Choose an e-commerce platform that           |
|                                     | supports robust security measures and        |
|                                     | integrates well with security tools.         |

The OWASP top 10 web application security risks (OWASP Top Ten | OWASP Foundation, n.d.). For more elaborate information about each risk, there are sub-pages for each of the risk explaining how I can tackle them.

| OWASP Category                          | Relevance to E-commerce  | Actions to Mitigate  |  |
|---|--|--|--|
| A01:2021 - Broken Access<br>Control     | Critical for preventing unauthorized access to user accounts, payment information, and admin functions.        | Implement role-based access control (RBAC), conduct regular access reviews, and use secure coding practices.                                   |  |
| A02:2021 - Cryptographic<br>Failures    | Essential for protecting sensitive data such as credit card details and personal information from exposure.    | Use strong encryption<br>standards (e.g., AES, RSA),<br>employ secure protocols<br>(e.g., TLS), and regularly audit<br>cryptography practices. |  |
| A03:2021 - Injection                    | Vulnerabilities like SQL injection and XSS can compromise sensitive data and manipulate application behaviour. | Use prepared statements and parameterized queries, validate and sanitize user input, and implement Content Security Policy (CSP).              |  |
| A04:2021 - Insecure Design              | Flaws in design can introduce vulnerabilities; secure design practices help identify risks early.              | Conduct threat modeling, apply secure design patterns, and involve security teams in the design phase.   |  |
| A05:2021 - Security<br>Misconfiguration | Misconfigurations during deployment can expose the application; regular audits are necessary.                  | Regularly review and test configurations, automate configuration management, and implement least privilege principles.                         |  |

| A06:2021 - Vulnerable and<br>Outdated Components      | Using outdated libraries can expose the application to known vulnerabilities; regular updates are critical.                | Maintain an inventory of components, apply security patches promptly, and use tools for vulnerability scanning.                             |
|---|--|---|
| A07:2021 - Identification and Authentication Failures | Flaws can lead to account takeovers; robust authentication mechanisms are necessary.                                       | Implement multi-factor authentication (MFA), enforce strong password policies, and use secure session management.                           |
| A08:2021 - Software and<br>Data Integrity Failures    | Ensuring the integrity of software updates and data is crucial to prevent manipulation and vulnerabilities.                | Use checksums or digital signatures for updates, implement secure CI/CD practices, and regularly audit data integrity.                      |
| A09:2021 - Security Logging and Monitoring Failures   | Effective logging is vital for detecting fraud and responding to security incidents.                                       | Implement comprehensive logging of critical actions, utilize centralized log management solutions, and regularly review logs for anomalies. |
| A10:2021 - Server-Side<br>Request Forgery             | SSRF vulnerabilities can lead to unauthorized access to internal resources, making them a concern for ecommerce platforms. | Validate and sanitize user-<br>supplied URLs, implement<br>network segmentation, and<br>monitor server-side requests.                       |

I plan to categorize security practices and risks using the MoSCoW method, prioritizing them from "must" to "could." This approach will help me implement the most critical measures first, followed by the less essential ones.

### **Security Testing**

Test the implemented security measures.

Static program analysis

Set up static code analysis to detect security breaches.

# What are the best practices for ensuring maintainability in eCommerce platforms?

### **Best Practices**

Maintenance plays a crucial role in the success of any eCommerce platform. According to (BigCommerceTeam, Ecommerce Website Maintenance Generates Wins Now and for Later, 2024), here are some essential maintenance tasks that should be prioritized once the project is live

| Aspect                      | Description   | Importance                   |  |
|-----------------------------|---|------------------------------|--|
| Mitigating cyber threats    | Regular updates to security                         | Reduces chances of cyber     |  |
|                             | software and plugins to                             | attacks and data breaches.   |  |
|                             | protect customer data from                          |                              |  |
|                             | hackers.  |                              |  |
| Maximizing website uptime   | Ensuring the site remains live                      | Prevents costly downtime     |  |
|                             | and accessible for                                  | and loss of business.        |  |
|                             | customers.  |                              |  |
| Preventing data loss        | Regular backups of                                  | Safeguards data in case of a |  |
|                             | databases and key systems.                          | catastrophe.                 |  |
| Maintaining compliance      | Staying updated with legal                          | Ensures compliance with      |  |
|                             | standards like PCI-DSS and                          | regulations, avoiding        |  |
|                             | GDPR.   | penalties.                   |  |
| Uptime consistency          | Ensuring site availability for                      | Crucial for seamless         |  |
|                             | users at all times.                                 | customer transactions and    |  |
|                             |   | user experience.             |  |
| Website security            | Applying security patches                           | Protects the site from       |  |
|                             | and maintaining an SSL                              | emerging security threats.   |  |
|                             | certificate.  |                              |  |
| Data backups                | Taking regular snapshots of                         | Provides insurance against   |  |
|                             | databases and key systems.                          | data loss and improves       |  |
|                             |   | recovery from cyber attacks  |  |
|                             |   | or system failures.          |  |
| Broken links                | Running reports to find and                         | Improves site quality and    |  |
|                             | fix broken links.                                   | customer experience.         |  |
| Page speed                  | Optimizing load times to                            | Impacts conversion rates and |  |
|                             | make the site faster.                               | customer satisfaction; slow  |  |
|                             |   | load times reduce sales.     |  |
| Updating outdated content   | Regularly auditing and                              | Increases customer           |  |
|                             | updating content to maintain                        | confidence and reflects      |  |
|                             | accuracy.   | business professionalism.    |  |
| Priority keyword rankings   | Reviewing and retooling SEO                         | Helps attract more           |  |
| (SEO)                       | to keep high search engine                          | customers through better     |  |
| B .:                        | rankings.   | search visibility.           |  |
| Promotions and price        | Regularly adjusting pricing to Ensures the business |                              |  |
| changes                     | stay competitive.                                   | remains competitive in an    |  |
|                             | N. d. d. d. d.                                      | open market.                 |  |
| More prone to cyber attacks | Neglecting updates makes                            | Increases the risk of data   |  |
|                             | ecommerce sites attractive                          | breaches and theft of        |  |
|                             | targets for hackers.                                | sensitive information.       |  |

| Slow website load times | Poorly maintained sites have | Conversion rates drop  |  |
|-------------------------|------------------------------|--|--|
|                         | slower load times.           | significantly with every extra   |  |
|                         |                              | second of load time.   |  |
| Higher costs due to     | Neglected websites are more  | Results in higher costs for  |  |
| recurring bugs          | prone to bugs and crashes.   | fixing issues and lost   |  |
|                         |                              | opportunities during   |  |
|                         |                              | downtime.  |  |
| Loss in customer trust  | Regular site issues erode    | Customers are less likely to   |  |
|                         | customer confidence.         | buy from a site they don't trust, especially with personal and financial |  |
|                         |                              |  |  |
|                         |                              |  |  |
|                         |                              | information.   |  |
| Outdated and misleading | Inaccurate information       | Regular content audits   |  |
| content                 | discourages purchases and    | maintain accuracy and  |  |
|                         | leads to customer            | customer satisfaction,   |  |
|                         | dissatisfaction.             | especially with new product  |  |
|                         |                              | launches.  |  |

### Best practices according to (Rawat, 2024)

| Best Practice                            | Description                                  |
|--|--|
| Understanding Your Website's Needs       | Regularly assess your website for outdated   |
|  | content, security vulnerabilities, and       |
|  | performance issues.                          |
| Setting Concrete Objectives              | Define specific goals for your website       |
|  | maintenance, such as boosting sales,         |
|  | enhancing user experience, or improving      |
|  | search rankings.                             |
| Prioritizing Critical Components         | Focus on the most important aspects of the   |
|  | website, including backups, security, and    |
|  | user experience, to save time and resources. |
| Creating a Consistent Maintenance        | Establish a regular routine for updates,     |
| Schedule                                 | security checks, and backups to ensure       |
|  | consistent performance.                      |
| Delegating Tasks Effectively             | Assign maintenance responsibilities to team  |
|  | members or specialists to ensure tasks are   |
|  | handled efficiently.                         |
| Documenting Procedures for Clarity       | Create step-by-step documentation for        |
|  | maintenance tasks to maintain clarity,       |
|  | consistency, and ease of training new team   |
|  | members.                                     |
| Budgeting Wisely for Tools and Resources | Allocate a budget for necessary tools,       |
|  | plugins, or services that support website    |
|  | maintenance and deliver a strong return on   |
|  | investment.                                  |
| Ensuring Robust Security Measures        | Implement security protocols such as SSL     |
|  | encryption, regular audits, and timely       |
|  | updates to protect customer data and         |
|  | enhance credibility.                         |

After reviewing both sources, I noticed that the non-functional requirement maintenance involves various other nonfunctional requirements like performance, security, and usability. Many of these practices have already been covered in their own sections of the research, and most are primarily relevant once the project is live.

## What are the best practices for improving usability in eCommerce platforms?

#### **Best Practices**

Usability plays a major factor in conversion rate. Therefore, it's important to make the website as attractive and user friendly as possible. Here are some best practises on the field of usability according to (Markovich, 2024)

| Best Practice                   | Description                                    |
|---------------------------------|--|
| Attractive Product Display      | Display products in a visually consistent and  |
|                                 | attractive way.                                |
| Personalize Suggestions         | Tailor product suggestions and deals to        |
|                                 | individual customers.                          |
| Implement clear navigation      | Make it easy for customers to find what        |
|                                 | they're looking for with intuitive navigation. |
| High-quality images             | Use professional, high-quality images that     |
|                                 | capture attention.                             |
| Insert enticing calls to action | Include clear and persuasive calls to action   |
|                                 | to encourage customers to make a purchase      |
|                                 | or explore more. ("Shop Now", "Buy Now",       |
|                                 | "Add to Cart", "Learn More" etc.)              |

<sup>&</sup>quot;Personalize Suggestions" is an interesting best practice because it needs to be considered before I begin the project, unlike the other practices that can be implemented at a later stage.

Here are most best practices according to (Cooper, 2023)

| Best Practices for Optimizing Website | Details  |
|---------------------------------------|--|
| Usability                             |  |
| Ease Navigation                       | User-friendly navigation is essential for driving conversions. Ensure visitors can easily find what they need. Consider implementing a sitewide search function and navigation tools that are easy to locate. Use a simple navigation bar with practical categories. The checkout button should be displayed on all pages.   |
| Streamlined Checkout                  | Lengthy checkout processes can lead to cart abandonment. Minimize the required information from users, such as using a checkbox to autofill shipping details. Allow guest checkouts to simplify the process and provide an option to save credit card information for returning customers.  Carewell's case study shows a direct correlation between stored payment options and a 200% increase in conversion rates. |
| Search Engine Optimization            | Optimize site search functionality to enhance product findability. Most users expect a   |
|                                       | search box in the top right corner. Use pre-   |

|                            | l gue a la l     |
|----------------------------|---|
|                            | filling based on popular searches and keep        |
|                            | search input visible during results display.      |
|                            | Implementing effective SEO strategies can         |
|                            | also drive relevant traffic to your site, thereby |
|                            | increasing conversion rates.                      |
| Optimized Page Load Speeds | Fast loading times are critical for retaining     |
|                            | customers. Ensure images are appropriately        |
|                            | sized (under 1000 pixels) and consider            |
|                            | compressing them to improve load speed.           |
|                            | Reduce unnecessary redirects as they slow         |
|                            | down the website.                                 |
| Optimize for Mobile use    | A mobile-friendly interface is essential for      |
|                            | modern e-commerce. Ensure compatibility           |
|                            | with mobile technologies and optimize for         |
|                            | mobile usability by increasing button sizes,      |
|                            | simplifying navigation, and offering features     |
|                            | like credit card scanning. Maintain a single      |
|                            | domain for both mobile and desktop versions       |
|                            | to avoid confusion. Successful mobile             |
|                            | optimization has led to significant increases     |
|                            | in conversion rates for companies like Ice        |
|                            | Jewellery.  |
| Accessible for all Users   |   |
| Accessible for all Osers   | Accessibility is key for a usable e-commerce      |
|                            | experience. Implement features like voice         |
|                            | search, keyboard navigation, and alt-tags for     |
|                            | images. Use high-contrast color schemes           |
|                            | and provide text alternatives for media.          |
|                            | Testing accessibility through crowdsource         |
|                            | testing can identify challenges and improve       |
|                            | user experience. Accessibility upgrades can       |
|                            | be low-cost and enhance overall usability,        |
|                            | thus increasing conversions.                      |
| Design your pages better   | Ensure a clear and straightforward pathway        |
|                            | to products. Differentiate information            |
|                            | between the homepage and product pages.           |
|                            | Highlight product information effectively and     |
|                            | organize content clearly. Including customer      |
|                            | ratings and reviews can help inform potential     |
|                            | buyers, increasing the likelihood of purchase.    |
|                            | Skullcandy's award-winning design focuses         |
|                            | on clarity and user engagement.                   |
| Focus on A/B Testing       | A/B testing allows you to identify usability      |
| -                          | issues through randomized experiments             |
|                            | comparing two variants. This cost-effective       |
|                            | method can help you understand user               |
|                            | reactions to changes in design or                 |
|                            | functionality, thus minimizing the risk of        |
|                            | negative impacts on user experience.              |
|                            | Insights from A/B testing and other usability     |
|                            |   |
|                            | testing methods can inform improvements           |
|                            | aligned with consumer needs.                      |

### Usability testing

Validate that my website is understandable and user friendly.

### Postface

So, what are the best practices in eCommerce. Now that I answered my sub-questions, I have a better idea of what I should do next.

### Page Loading Speeds

For page loading speeds there are many tips in its own section. I would recommend going through them and prioritize them using the MoSCoW method. Something noticeable from this section of the research is that I want my pages to load within 1 second (with a maximum of 2 seconds if it really doesn't work out). This is based on research on conversion rates. See the dedicated section on page loading speeds for more details.

Page Loading Speeds: 1 second (worst case scenario max 2 seconds)

#### Concurrent Users

I've decided to build a website with the scalability of Bol.com. Based on my calculations, this means the website needs to be capable of handling 1 million concurrent users.

Concurrent Users: One Million

### Hosting

For hosting, the three hosts left were: **Cloud Hosting, Enterprise-Grade Hosting** and **VPS Hosting**. I decided that it would be more convenient to choose **Cloud** or **Enterprise-Grade** hosting because they usually have auto-scaling built in which is amazing in my case. Therefore VPS hosting is more of a last resort.

Hosting Choice: **Cloud Hosting** or **Enterprise-Grade Hosting** (VPS hosting if both don't work out)

#### **Architecture**

My choice for the architecture should be one of the following: **Microservice Architecture**, **Three-Tier Architecture**, **Headless Architecture**. In short, scaling a **Three-Tier** is not as convenient as scaling a microservice architecture, but it's simpler to develop and manage. The headless architecture is completely different than these two architectures, and shines in its omnichannel possibility. However, I don't need that, but that doesn't make it a bad choice.

Meaning the decision is between **Microservice Architecture** and **Headless Architecture**. I am choosing for the Microservice Architecture for the sake of that I want to learn better how to implement it.

Architecture Choice: Microservices (But Headless is also a very good choice)

### Security

For security I collected many tips I could work on later after the project has a walking skeleton. Something to keep in mind in the project starting phase is to pick a host with many built in security functionalities so that I don't have to implement them myself (Think of **DDoS protection** for example). And for example, for authentication, choose a technology that allows **Multi Factor Authentication**. More tips in its own dedicated section

### **Usability**

For usability I mainly found tips to enhance the user experience, but I can also derive design choices from the tips I found.

Important Usability Design Choices: Show Personalised Products, Optimize Search Engine, Mobile and PC interface.
